Answers and talk notes

Math is In My World

What your student is learning

Tonight we draw a real-world money problem as a tape diagram or a table, and then solve it with decimals.

Answers

Ask your student to explain before you look.

1. **B.** Going and coming back, which is two rides. Going and coming back, which is two rides. A round trip costs two fares.
2. **A.** $5.50. 75 cents + 75 cents is 150 cents, which is $1.50. $2 + $2 + $1.50 = $5.50.
3. **C.** $4.05. 3 × $1.35 = $4.05, because 3 × $1 = $3 and 3 × 35 cents = $1.05.
4. **D.** $2.50. $10.00 ÷ 4 = $2.50, because 4 × $2.50 = $10.00.
5. **B.** 85. 8.5 × 10 = 85. Multiplying by 10 moves every digit one place to the left.
6. **C.** $11.00. One round trip is $2.75 + $2.75 = $5.50. Two round trips are $5.50 × 2 = $11.00.

Talk about it

How many equal parts does your tape diagram have, and what does the whole tape stand for?

Home mission

A different situation: pick a snack price like $1.50. Ask your student to draw a tape with 4 equal parts of $1.50. What does the whole tape stand for? How much is it?

When they are stuck, ask

- Can you draw the problem before you solve it?
- What is one part, and how many parts are there?
- Are your decimal points lined up?

Try not to say

- Don't bother drawing it, just do the math.
- Ignore the decimal point and put it back later.
- The picture is for little kids.
