Compare Ratio Relationships

What your student is learning

Tonight we compare two rates by scaling BOTH of them to the same amount — a benchmark — instead of dividing.

Answers

Ask your student to explain before you look.

1. **C.** 3. 4 × 3 = 12, so the scale factor is 3.
2. **B.** $30. The scale factor is 3, so the cost is $10 × 3 = $30.
3. **C.** 12. 12 ÷ 6 = 2 and 12 ÷ 4 = 3, and no smaller number works for both, so the answer is 12.
4. **A.** 600 miles. 3 × 4 = 12, so the distance is 150 × 4 = 600 miles.
5. **B.** Machine B, 12 bottles is more than 10 in 4 minutes. Machine A in 4 minutes fills 10 bottles, so Machine B, 12 bottles is more than 10 in 4 minutes, fills faster.

Talk about it

Why did you pick 12 lemons as the amount to compare?

Home mission

Pretend one pizza shop sells 2 slices for $3. Another sells 3 slices for $5. Ask your student to pick a benchmark both deals can reach. Which shop is the better deal at that benchmark?

When they are stuck, ask

- What number can both of these reach?
- Did both numbers in the rate get multiplied by the same factor?
- Now that one quantity matches, which one wins?

Try not to say

- The bigger number is the faster one.
- You can compare them just as they are.
- Scale one of them and leave the other alone.
