Answers and talk notes

Write Equations to Represent Relationships Between Two Variables

What your student is learning

Tonight we turn a real situation into an equation — spotting the rate that MULTIPLIES and any starting amount that ADDS.

Answers

Ask your student to explain before you look.

1. **D.** c = 2m. c = 2m shows $2 for each of m miles.
2. **B.** y = 2x + 5. y = 2x + 5 matches, because $2 is multiplied by the hours and $5 is added once.
3. **C.** 11. y = 11, because 2 × 3 = 6 and 6 + 5 = 11.
4. **A.** 5. 5 is the starting amount, because it is added once.
5. **B.** $48. $48, because 16 × 3 = 48.

Talk about it

Which part of your equation multiplies and which part is added once? How do you know?

Home mission

Pretend a parking spot costs $5 to enter plus $2 for each hour. Ask your student for the cost of 4 hours. Which number is paid once, and which number repeats?

When they are stuck, ask

- Which amount happens every time, and which happens once?
- Does the rate multiply the variable, or get added to it?
- Test your equation on one row you already know.

Try not to say

- Add all the numbers in the problem together.
- A monthly fee gets added once, whatever the months.
- You do not need to test the equation.
