Math is Ingenuity — Homework

Lesson 10-4 • Standard MPP.4

Name: ________________________ **Period:** ______ **Date:** _____________

Today's Goals

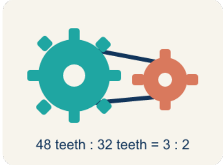
Content: I can use ratios and models to explain how the Penny Farthing and gear-driven bicycles were ingenious solutions to a real problem.

Language: I can explain a gear ratio using the words rotation, teeth, and 'for each ___, the wheel turns ___.'

Key Words

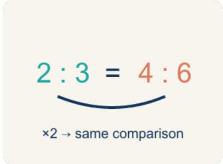
ingenuity (ingenio) — Coming up with different, and sometimes unique, solutions to problems.

rotation (rotación) — One full turn of a wheel, gear, or pedal all the way around.



gear (engranaje) — A toothed wheel that passes motion to another toothed wheel through a chain.

ratio (razón) — A comparison of two quantities, like pedal rotations to wheel rotations.



equivalent ratios (razones equivalentes) — Ratios that make the same comparison using different numbers.

Practice

Show your work. Use the blank space under each problem.

1. On the Penny Farthing, what is the ratio of pedal rotations to front-wheel rotations?

A. 1 to 1
B. 1 to 2
C. 1 to 4
D. 2 to 1

2. How far does the Penny Farthing travel with each pedal rotation?

A. The height of the rider

B. The length of the perimeter of the front wheel
C. The length of the pedal
D. It does not move a fixed distance

---

3. The pedal gear turns 48 teeth per rotation. The largest rear gear needs 32 teeth for one full rotation. How many rotations does the rear wheel make for each pedal rotation?

A. 0.5 rotations
B. 1.5 rotations
C. 2 rotations
D. 16 rotations

---

4. The smallest rear gear has 12 teeth. How many rotations will the rear wheel make for each rotation of the 48-tooth pedal gear?

A. 0.25 rotations
B. 3 rotations
C. 4 rotations
D. 36 rotations

---

5. You are about to ride up a steep hill. Which rear gear should the chain be on, and why?

A. The 12-tooth gear, because 4 rotations per pedal is always better
B. The 32-tooth gear, because it makes the bike go faster
C. It does not matter which gear you use on a hill
D. The 32-tooth gear, because 1.5 rotations per pedal makes pedaling easier at slow speeds

---

6. Why do you think the larger gear makes it easier to pedal at slower speeds?

---

7. With the chain on the 12-tooth gear, the rider makes 10 pedal rotations. How many rotations does the rear wheel make?

A. 14 rotations
B. 22 rotations
C. 40 rotations
D. 120 rotations

---

8. When the chain is on the largest gear the rear wheel makes 1.5 rotations per pedal rotation; on the smallest gear it makes 4. What do you notice about the size of the wheel gears and the distance the bike travels?

---

9. The pedal gear has 48 teeth. Complete the table of wheel rotations per pedal turn.

Rear gear (teeth)	Ratio 48 ÷ teeth	Wheel rotations per pedal turn
12	48 ÷ 12	
16	48 ÷ 16	
24	48 ÷ 24
